Program Coordinator Review

SECTION A: SYSTEM DESIGN AND ALGORITHM

Workspace flow:

VS code → Google Colab → Github Repository
 → Google Drive → Student Portal Submission.

Explanation:

- i. VS code: Write, edit code with syntax highlighting and debugging.
- ii. Google Colab: Runs Jupyter notebook, python online
- iii. Github Repo: Store project files online.
- iv. Google Drive: Store pdf's and notebook files and share using links.
- v. Student Portal: Submit all links and files

CONTINUATION SHEET

OFFICIAL ANSWER SHEET

Use additional copies if required

SECTION B: PYTHON FUNDAMENTALS

→ } $a = 25 \rightarrow$ a stores the value 25
 $b = a \rightarrow$ b refers to the same value as a.
 $c = 25 \rightarrow$ c, a new variable refers to 25

All the variables a, b, c refer to the same value.

$a = b = c = 25$

2.1] Student performance Analytics:
Input: Student dataset containing student ID, Name, Attendance Percent, Diary entries, Tasks completed, Assignment score, and lab score.

- Steps:

1. Start
2. Read student dataset.
3. Check whether dataset is empty.
 - If the dataset is empty display "No data found" and stop.
4. Check records for missing values.
 - If there are missing values, report missing data or skip the records.
5. Read attendance, diary entries, tasks completed, assignment score and lab score for every student and calculate readiness score using formula for every student.
6. Classify students based on their readiness score.
7. Repeat step 6 for every student.
8. Calculate average performance of every student ^{dept.}.
9. Find the student with highest readiness score.
10. Find students who need academic support.
11. Display:
 - Department's average performance.
 - Top performing student.
 - Students needing academic support.
12. Stop.

- Output:

- Readiness score of every student
- Performance band.
- Department average performance.
- Top Performer.
- List of students needing support.

Edge Cases:

- Empty datasets.
- Invalid attendance or scores. (< 0 or > 100).

2.3]

>] names = ["Asha", "Riya"]
In 'names' variable, a list is stored.

same_names = name
The 'same_names' points to the same object as 'names'.
same_names.append("Neha")
append() is used to add a string at the end of list and
it changes both variables.
Final list: ["Asha", "Riya", "Neha"]

Q.4.]

→ Iteration 1: score = 38
is 38 < 40? → Yes
band = support.

Iteration 2: score = 62
is 62 < 40? → No
is 62 < 70? → Yes
band = Developing

Iteration 3: score = 81
is 81 < 40? → No
is 81 < 70? → No
is 81 < 90? → Yes
band = strong

Iteration 4: score = 94
is 94 < 40? → No
is 94 < 70? → No
is 94 < 90? → No
Else:
band = Excellent.

Q.5.]
→ def readiness_score(attendance, diary_entries, task_count):
score = (attendance * 0.6) + (diary_entries * 2) +
(task_count * 3).

if score > 100:

score = 100

elif score < 0:

score = 0

else:

score = score

return score.
